1 Introduction **1**

2 Implementation of the lexical analyser **2**

1 Introduction

The project aim is to implement a compiler for a 'simple' imperative language named *IMP*. Like any imperative programming language, *IMP* is structured of mainstream features such as *keywords* (`if`, `while`, ... statements), the use of *variables*, the use *numbers* and the use of *comments*. The form of these features follows some defined rules :

- a *variable* is a sequence of alphanumeric characters that must start by a letter.
- a *number* is a sequence of one or more digits.
- a *comment* must start by the combination `(*` and ends by the reversed combination `*)`.

The compilation scheme is generally divided in three main phases : analysis, synthesis and optimization. The phases are themselves composes of different steps. For instance, the analysis phase is composed of *lexical analysing* step (or *scanning*), a *syntax analysing* step (or *parsing*) and a *semantic analysing* step. In this assignment, the focus is set on the *analysis phase*.

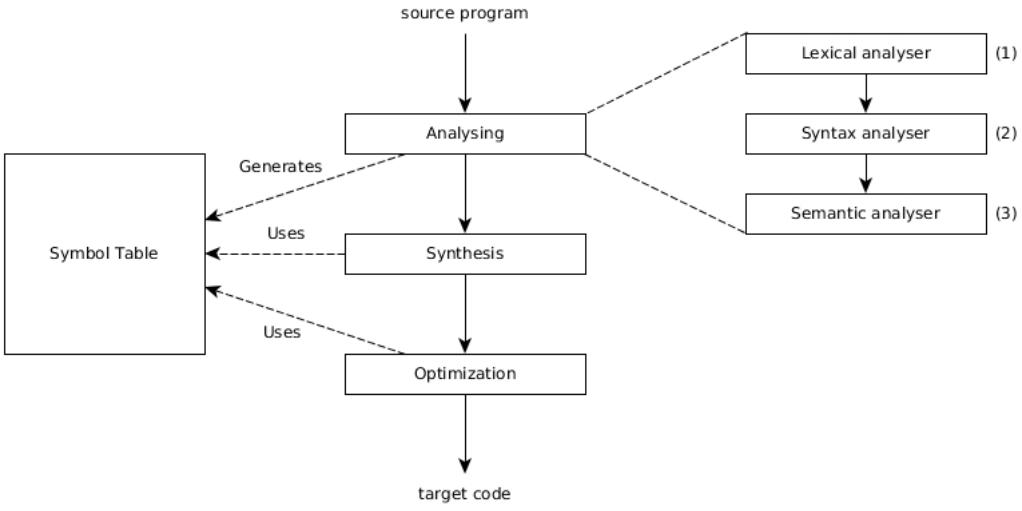

Figure 1 - Compilation phases.

2 Implementation of the lexical analyser

In the so called "Dragon book"[1] the *lexical anlyser* is defined as follow :

«The *lexical analyser* reads the stream of characters making up the source program and groups the character into a meaningful sequence called *lexemes.*»

A *lexeme* can be defined as a tuple which contains both a *token name* and the associated value. The sequence of *lexemes* generated by the *lexical analyser* will be used by the following step. In addition, the *lexical analyser* will generate a very useful tool, that will be used by all the other steps (as shown in fig 1.), called a *symbol table*. The role of the *symbol table* is to store every variable encountered while scanning the source code and the line where it appears for the first time.
